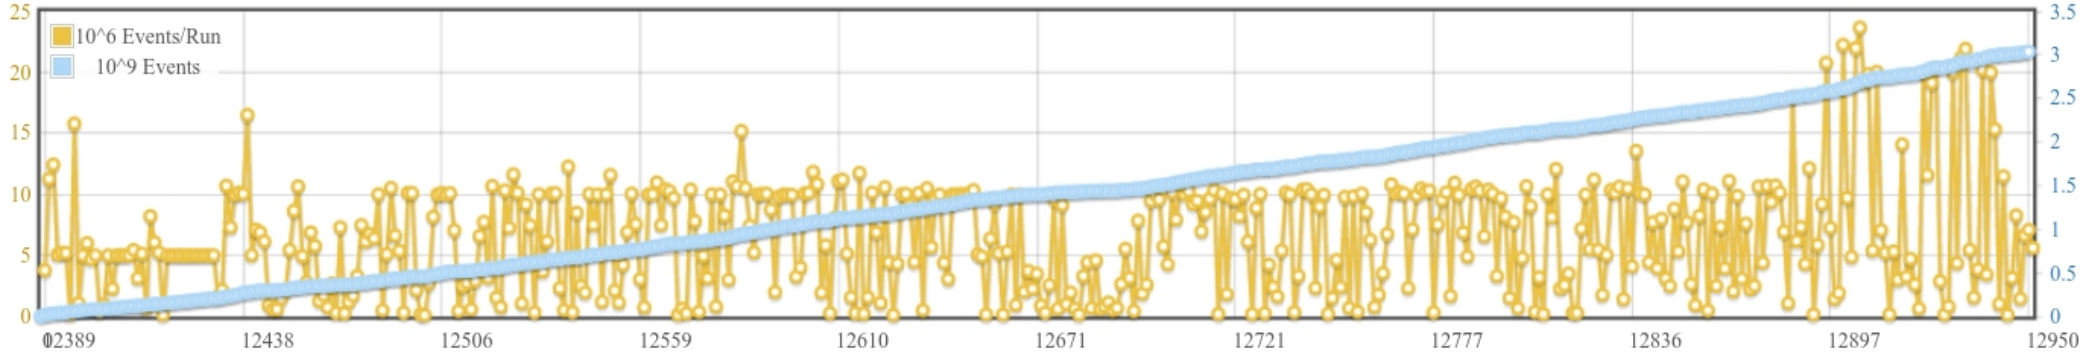
BONuS12-RTPC Calibration For RG-F

M. Hattawy
(On behalf of RG-F)

RG-F Pass1v2 Readiness Review, June 17th, 2022, JLab

Data Scope



Showing runs: 12389 - 12951. 472 runs per page. Total runs: 472

Data Range:

- Summer run:

12389 – 12434 (Out-bending 1 pass)

12435 – 12443 (In-bending 1pass)

12447 – 12951 (In-bending 5 pass)

Beam Energy	Target	Summer 2020
1 Pass Data	H2	185M
	D2	45M
	4He	44M
	Empty	22M
5 Pass Data	H2	266M
	D2	2355M
	4He	51M
	Empty	45M
		3013M

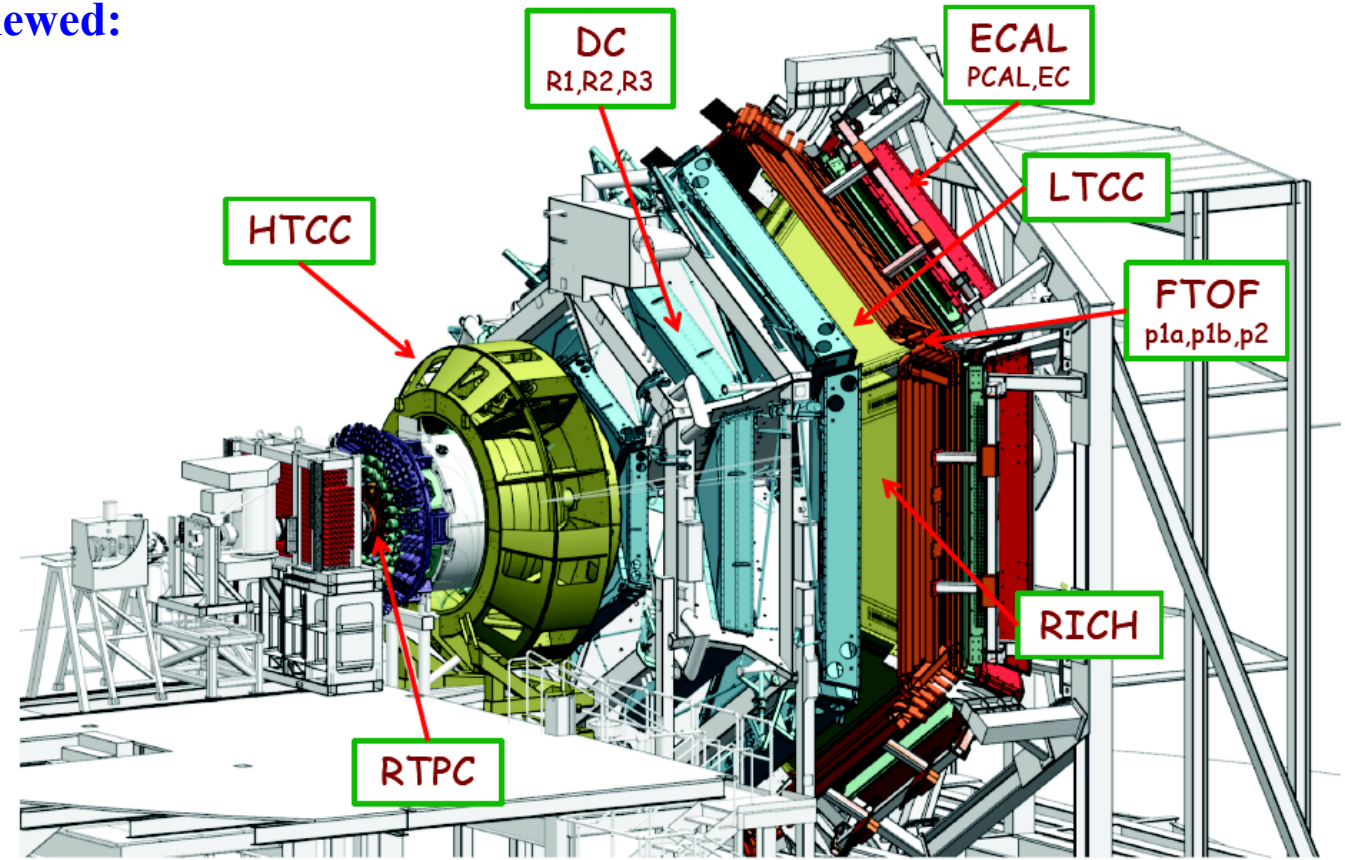
Calibration Scope

*** Detectors calibration to be reviewed:**

- RTPC
- HTCC
- DC
- LTCC
- RICH
- FTOF
- EC

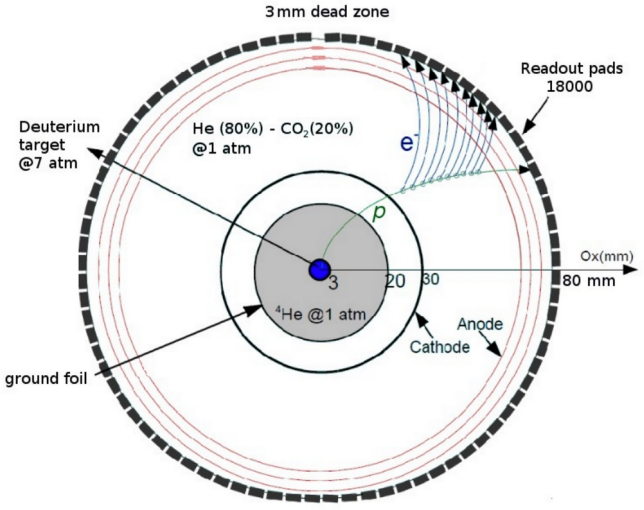
*** Detectors to be later calibrated (pass2):**

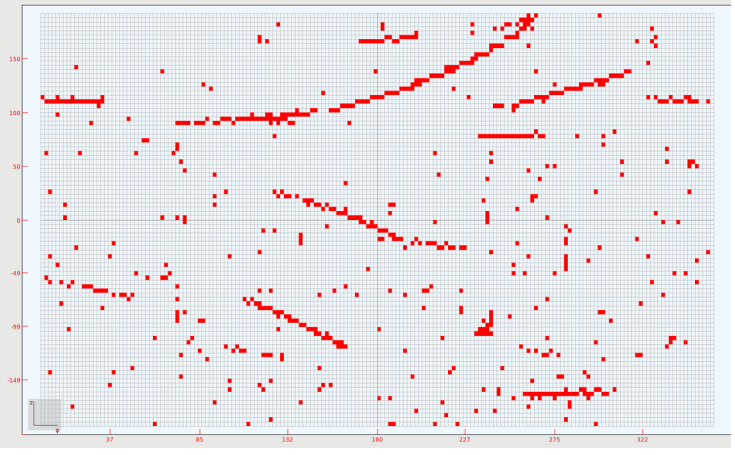
- FMT (3 layers)
- CND + CTOF



RTPC Calibration

RTPC Calibration





- Work principle:

Charged particle ionizes the gas atoms
→ Under EM field, released electrons follow their drift paths at a certain drift speed
→ Amplifications via the 3 GEM layers
→ Readout board → MVT FEU electronics →

Recorded info

- Pad # → Pad (x,y,z)
- Time
- Signal height

- Offline reconstruction:

* Time and Pad location
→ 3D reconstruction of track
→ vector p/q, vz, vertex time

* Signal height — Pads' gain (G_i) →

$$\left\langle \frac{dE}{dX} \right\rangle = \frac{\sum_i \frac{ADC_i}{Gi}}{vtl}$$

RTPC Track Reconstruction

1. Track Finding: Hits chaining into contiguous collections, i.e. tracks
2. Time shifting: Each chain of hits for a track is shifted in time, such that the first ionization starts at the cathode.
3. Reconstructing the hit position:

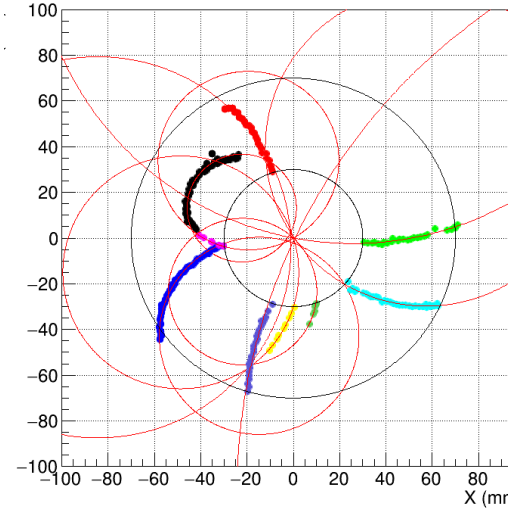
(Pad # → Pad (x,y,z), Time) → The original location of the ionization can be determined as:

$$r\left(t,z\right) = \sqrt{r_{max}^2\left(1-x\right) + r_{min}^2 x}$$

$$x = \frac{t - a_t}{b_t}$$

$$\Delta\phi\left(r,t,z\right) = a_\phi + b_\phi \ln\frac{r_{max}}{r}$$

→ Hit (r, ϕ, z)
* at the ionization point in the drift region

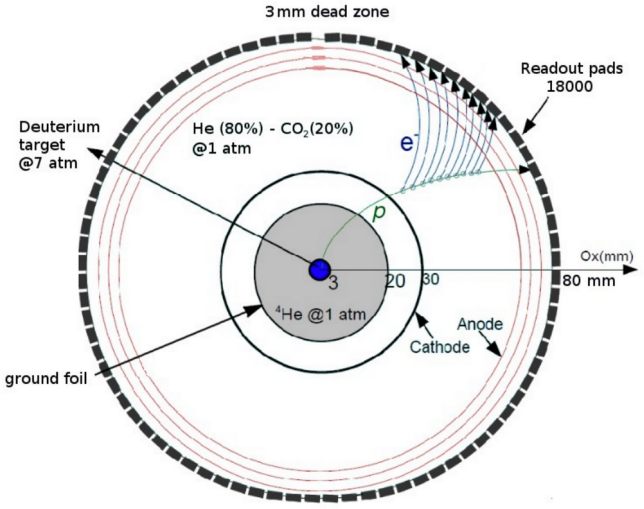


* a, b, parameters are z-dependent parameters initially calculated by a simulation of the magnetic field in Garfield++ and re-tuned using real data (next slide).

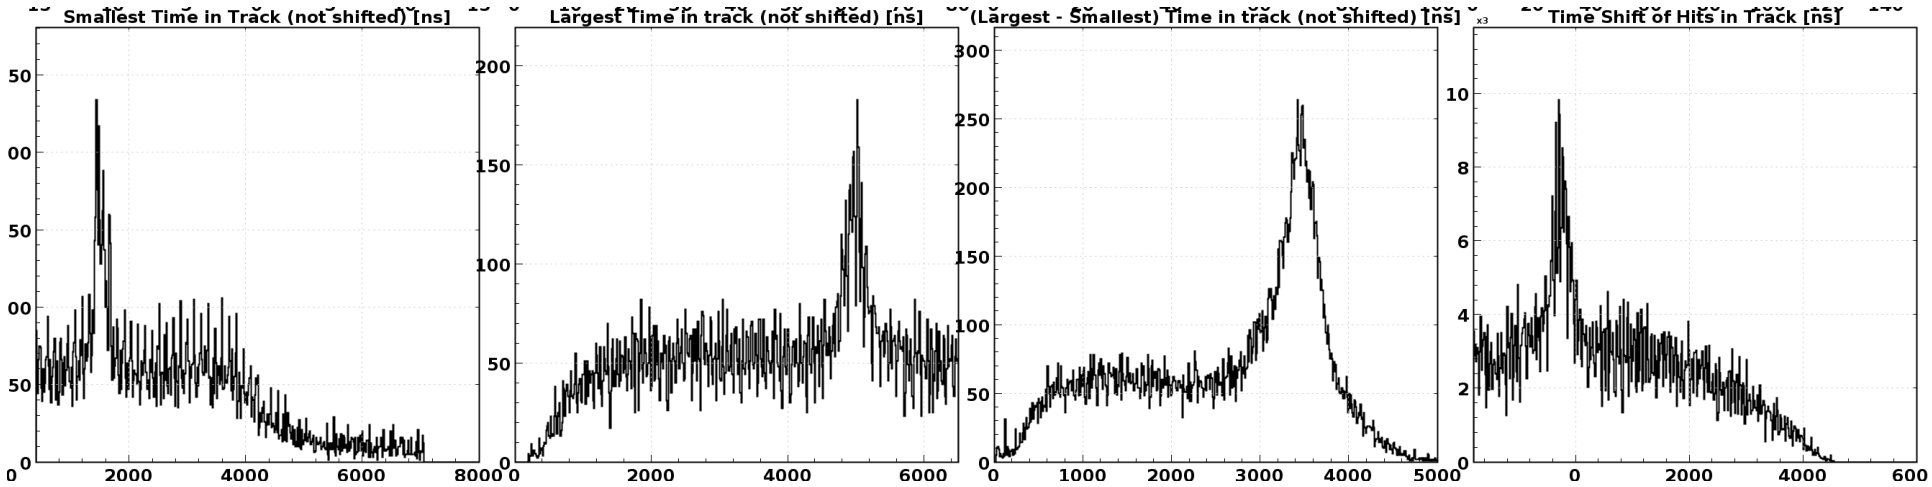
a_t = “Smallest Time” = time offset
b_t = the max. drift time (Largest time - Smallest Time)
a_ϕ (comes entirely from the GARFIELD++, the drift between GEM1 and Padboard)
b_ϕ = tan(θ_Lorentz)

4. Helix Fitting → Track’s p/q, vz, ...

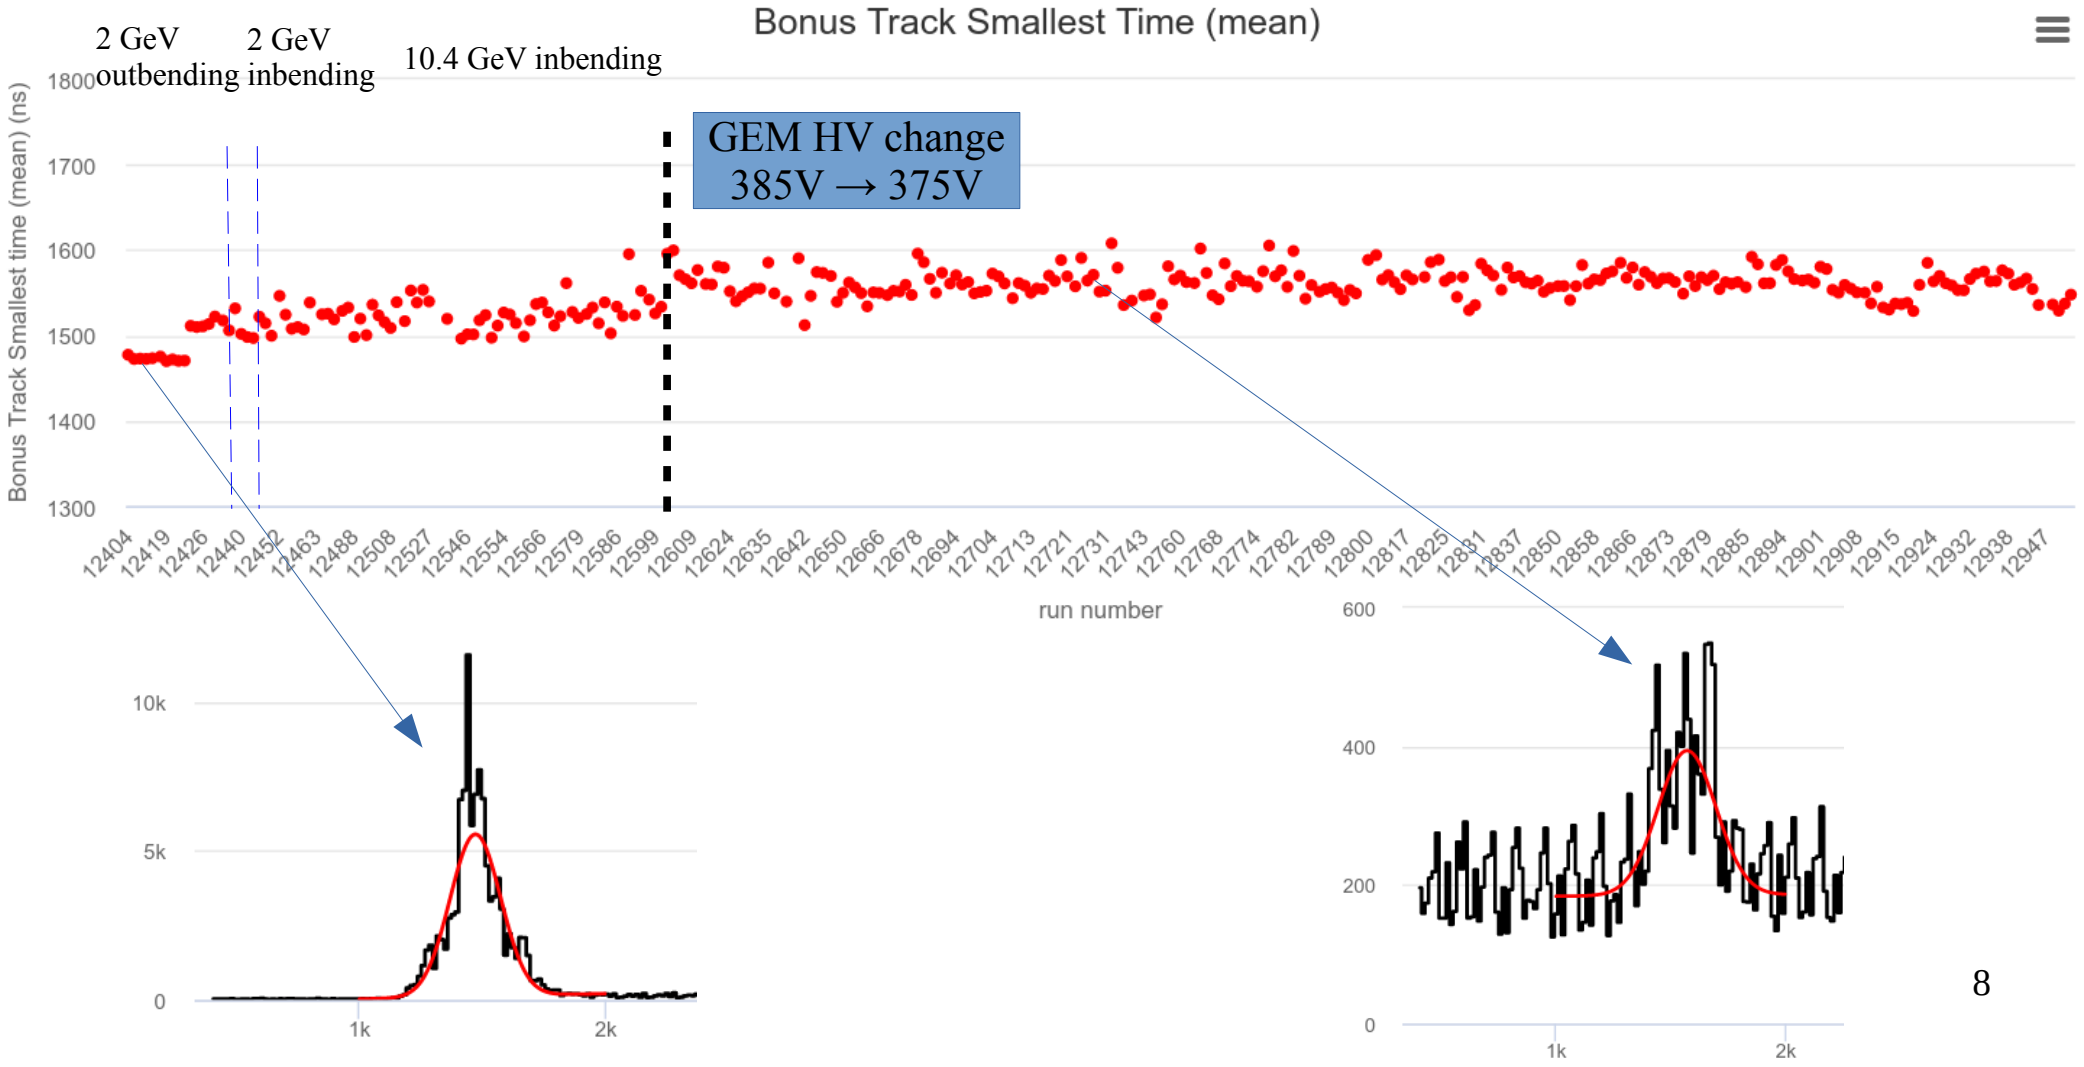
BONuS - Timing



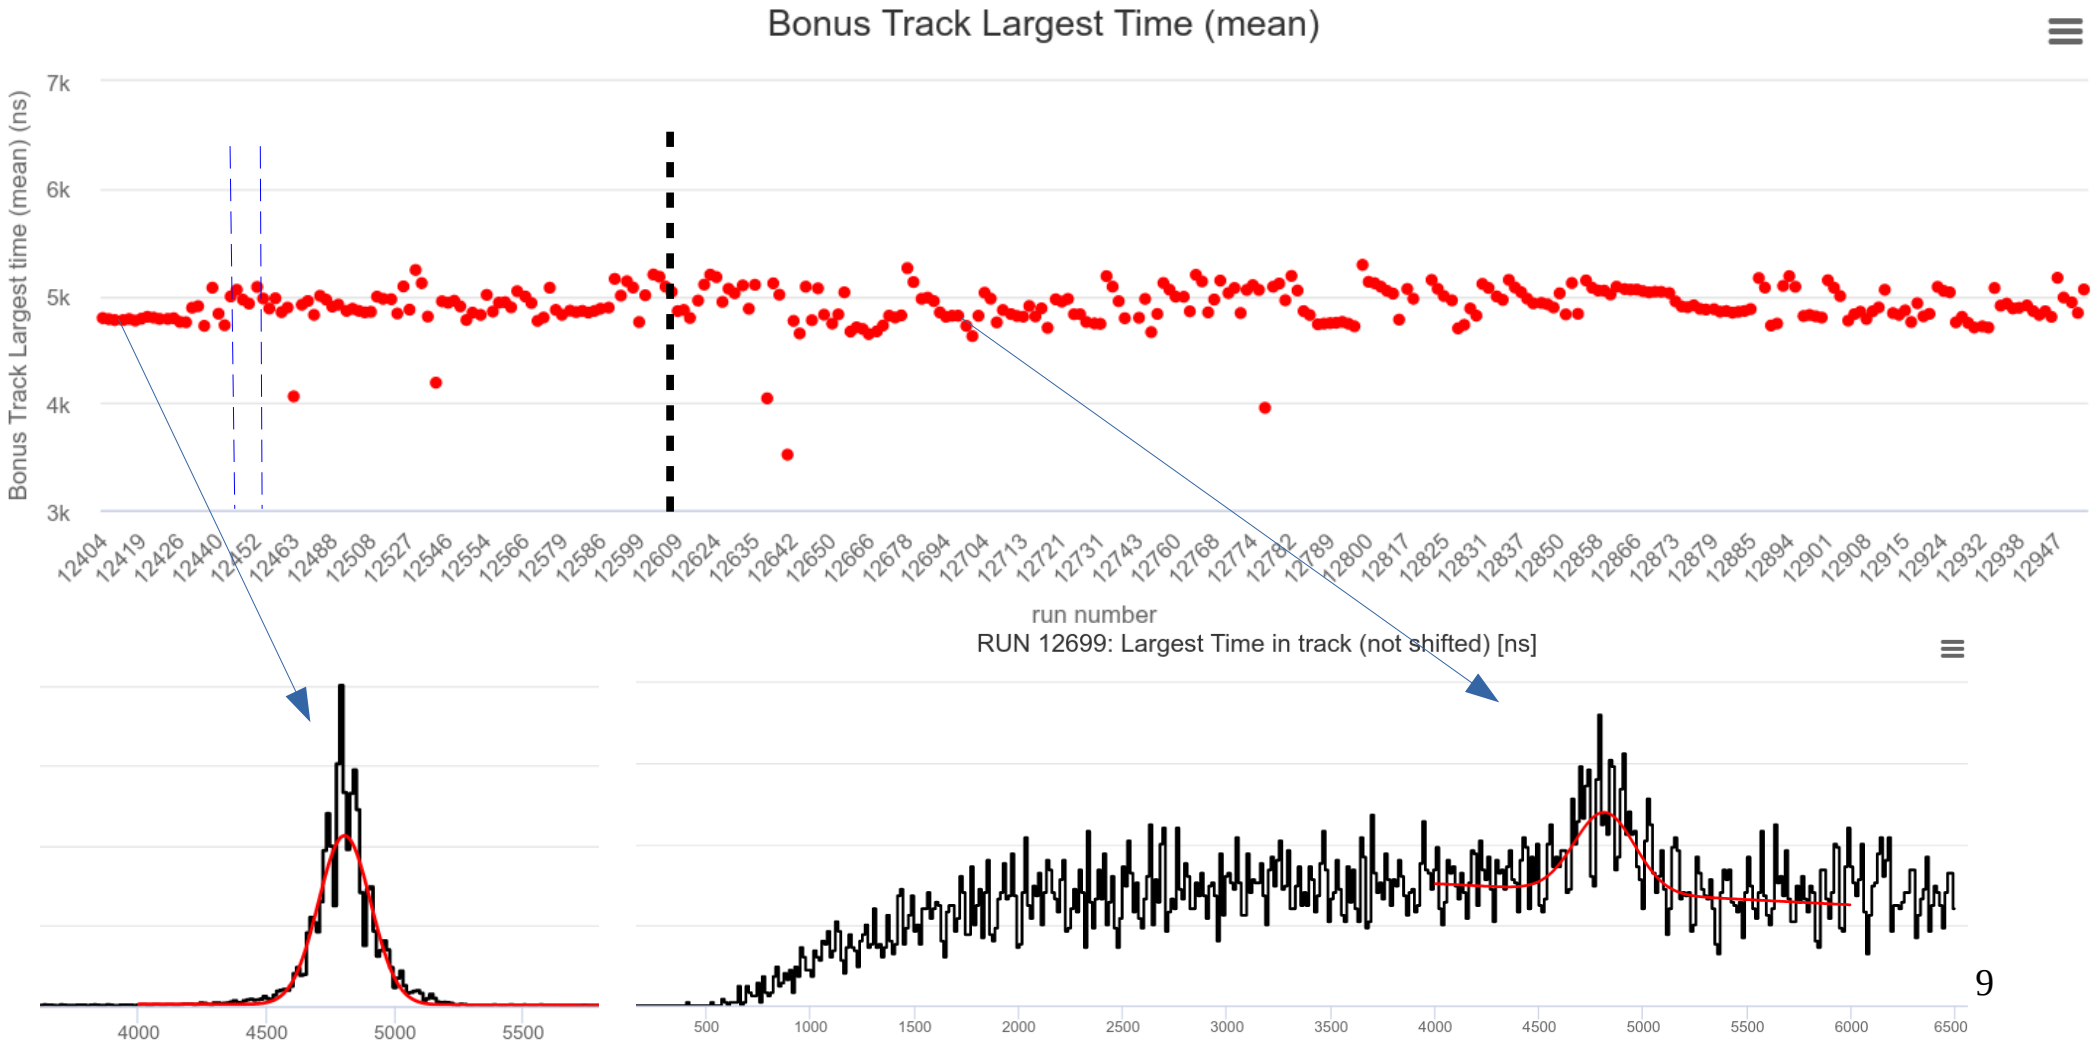
- Smallest time → Timing offsets between the trigger and the RTPC.
- Largest time → Sum of offset + maximum drift time
- Largest - Smallest time → maximum drift time from cathode to GEM1
- Time shift → Difference between measured largest time within a track and that expected for an in-time track



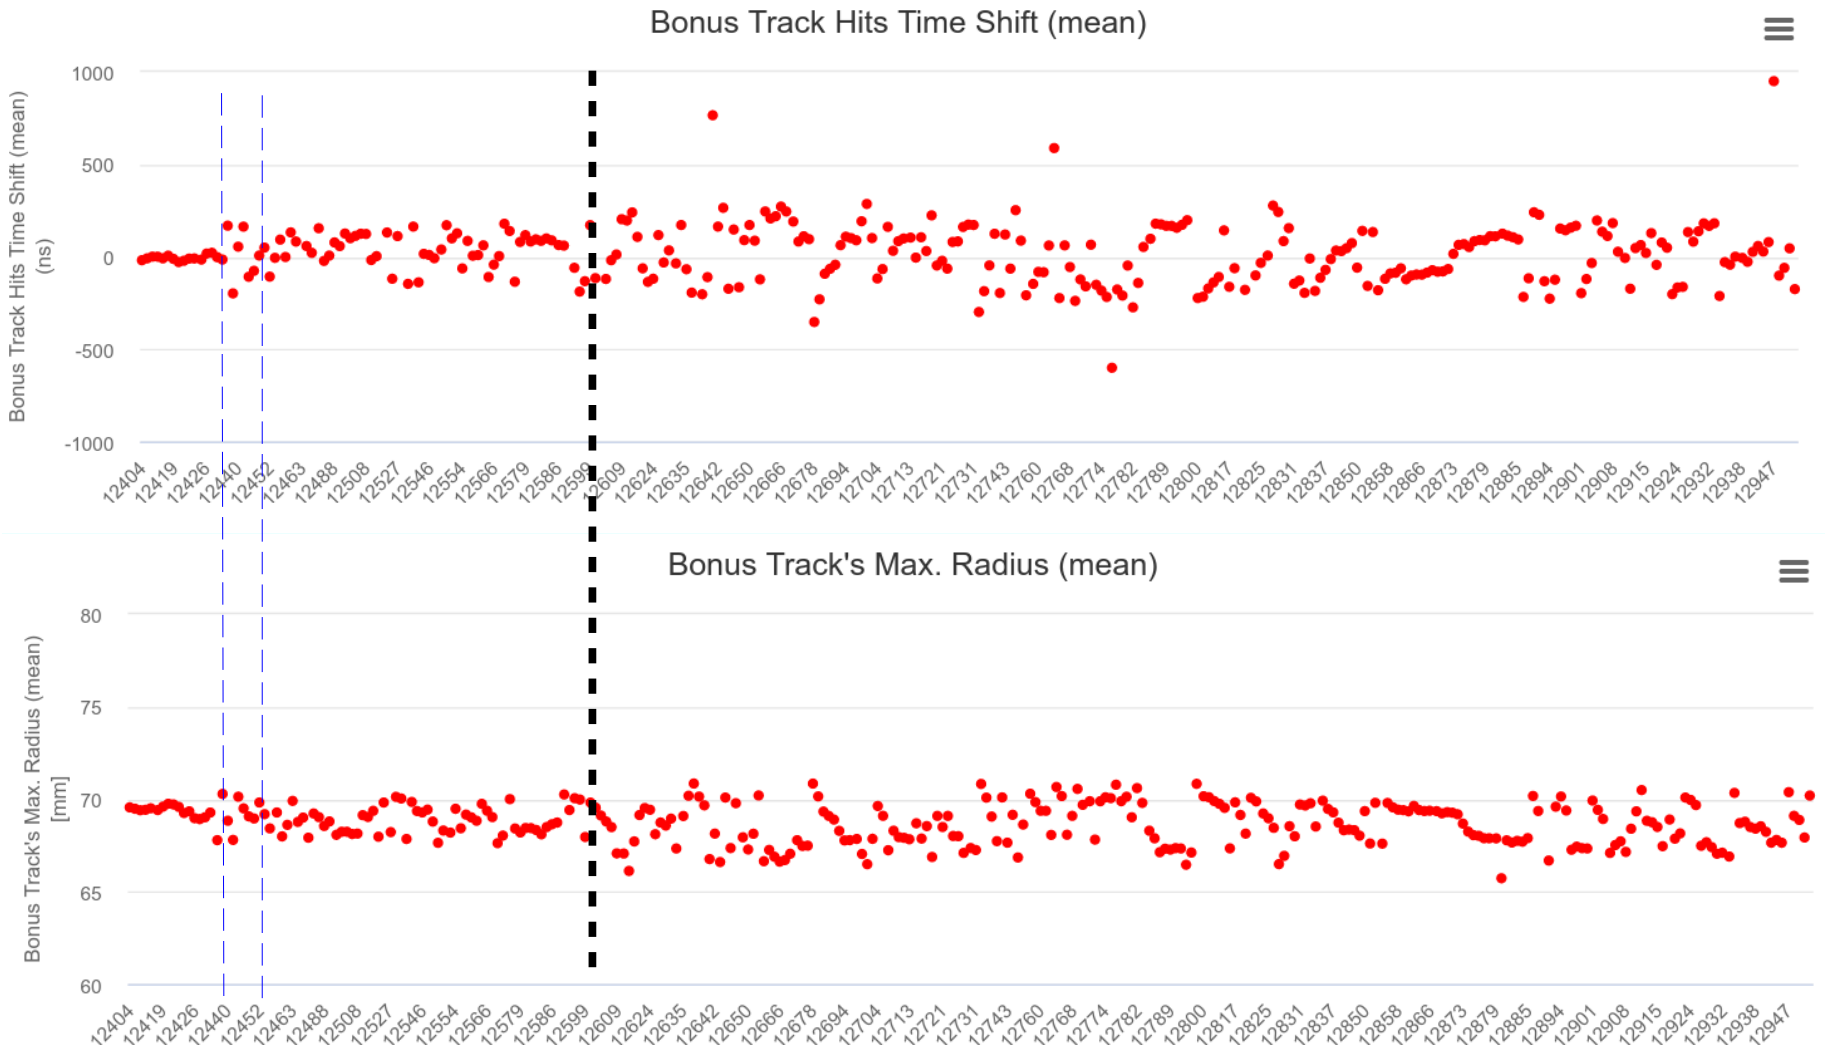
BONuS – Timing (Smallest Time)



BONuS – Timing (Largest Time)

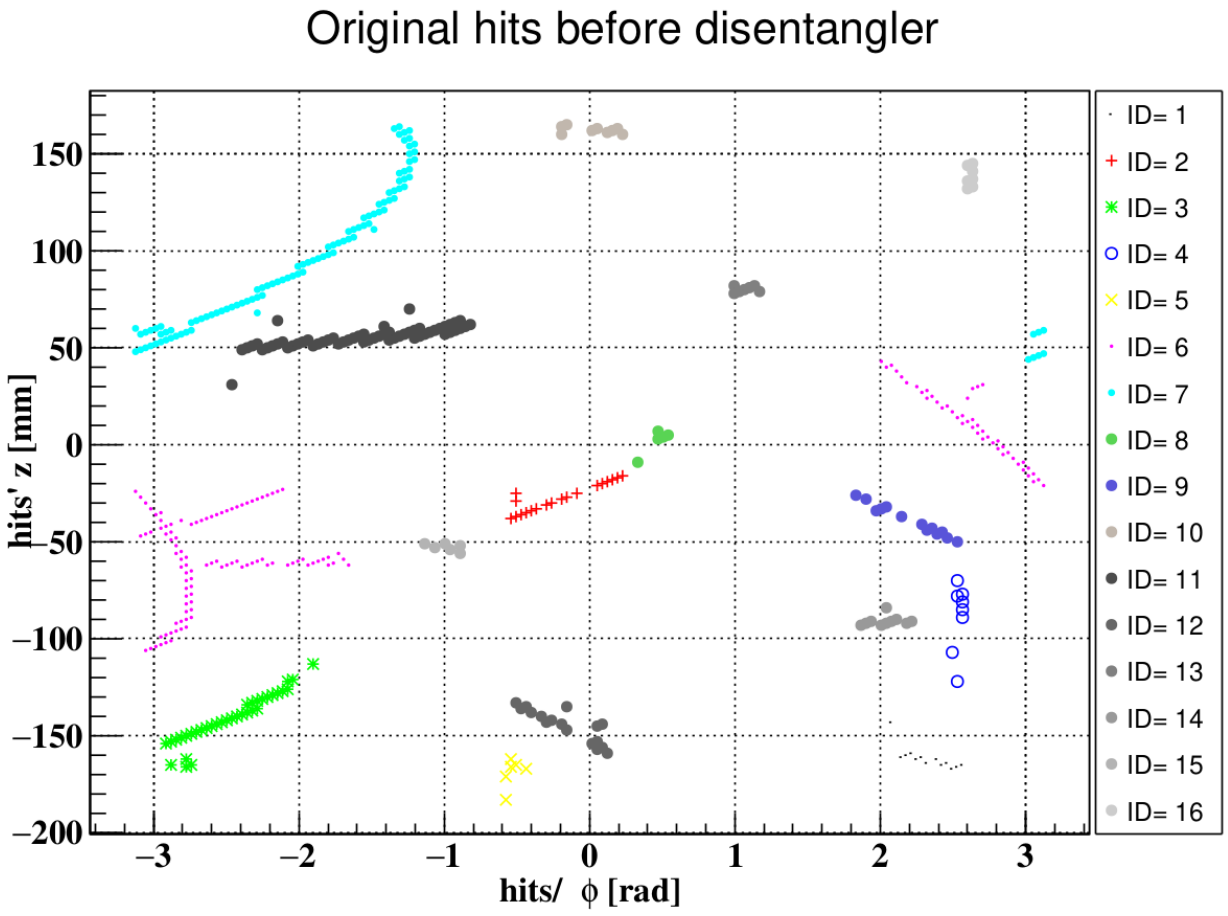


BONuS – Timing Quality Timelines



Updates on the RTPC Track Reconstruction

Tracks' Disentangler: Distinguishing the crossing tracks.



Updates on the RTPC Track Reconstruction

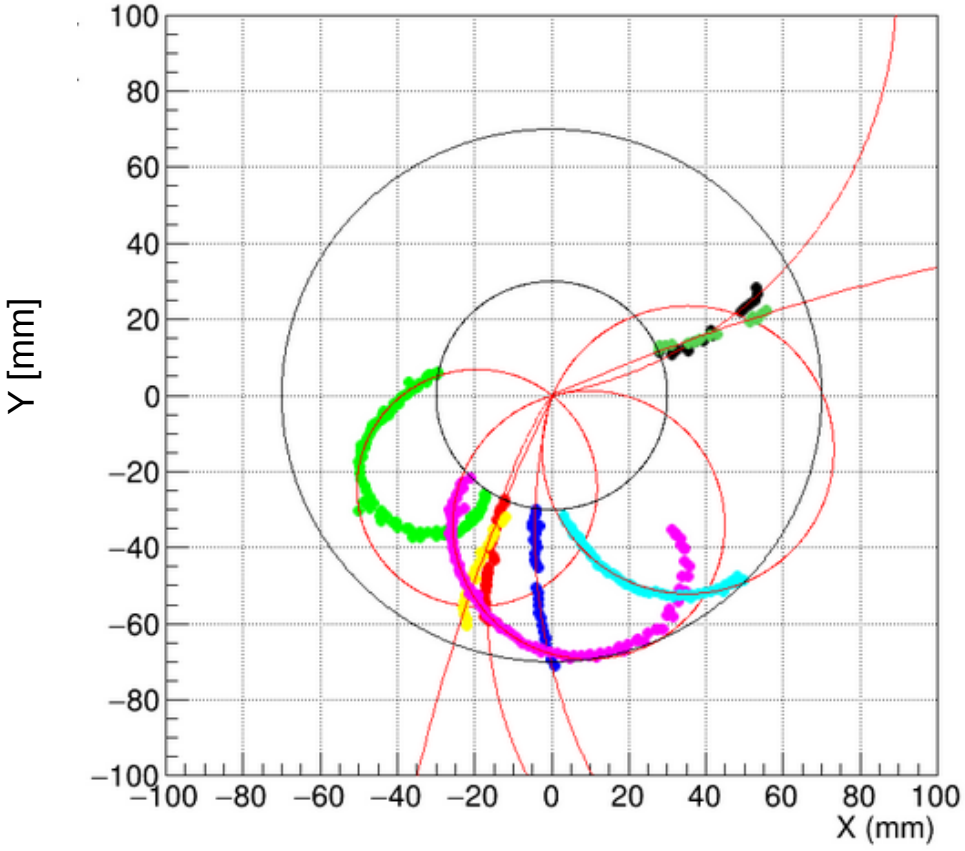
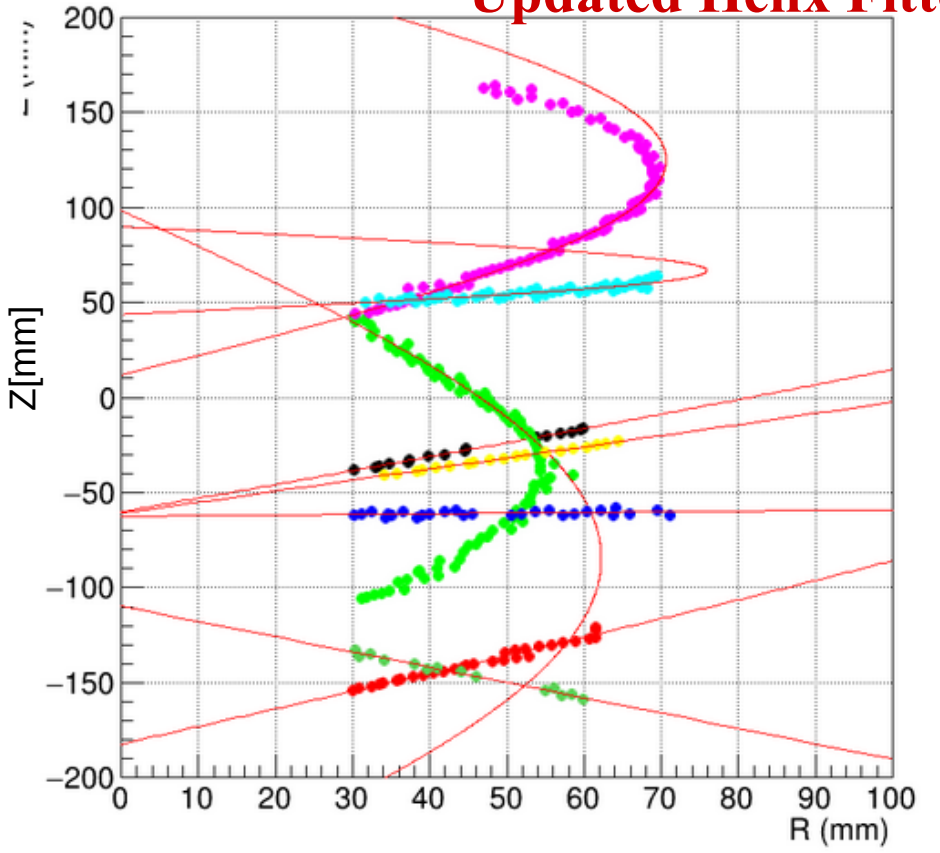
Back-benders and tracks crossing the seam of the RTPC: (+40% more tracks were reconstructed)

Updated Helix Fitter





Lorentz Angle Calibration

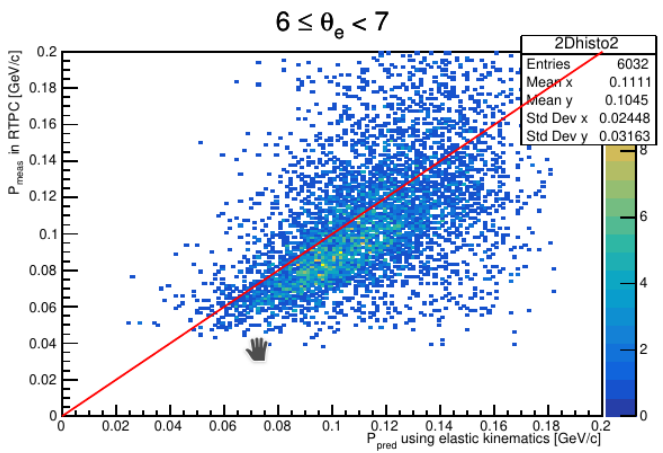
→ Use radiative e-p elastic scattering (beam bremsstrahlung) at 1-Pass to calibrate the RTPC (θe- [5°,8°]).

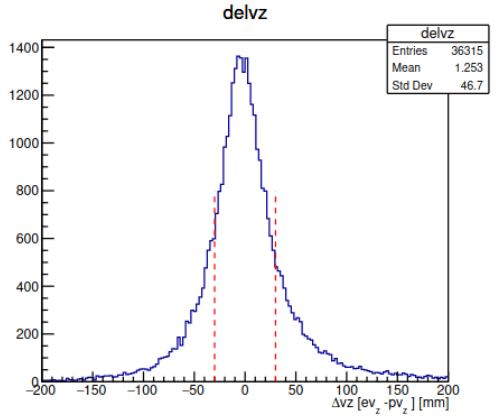
→ Then calculate the energy of the gamma simply ASSUMING that the event was elastic.

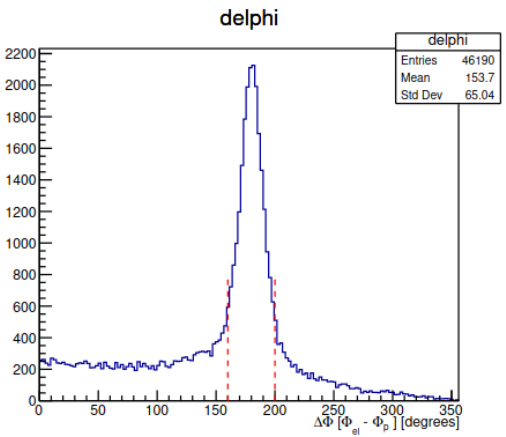
→ Simple, first estimation for energy loss applied, but will be refined in the future.

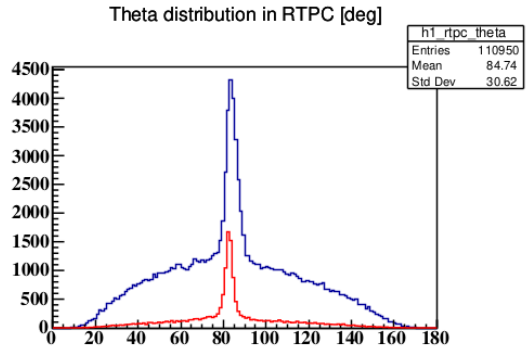
→ Modify the Lorentz angle until we get the best agreement between the measured and the predicted momentum for protons in H(e,e'p)γ.

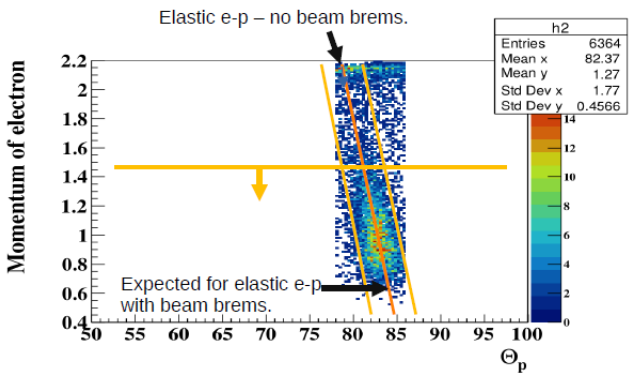
2.14 GeV on H_2 target



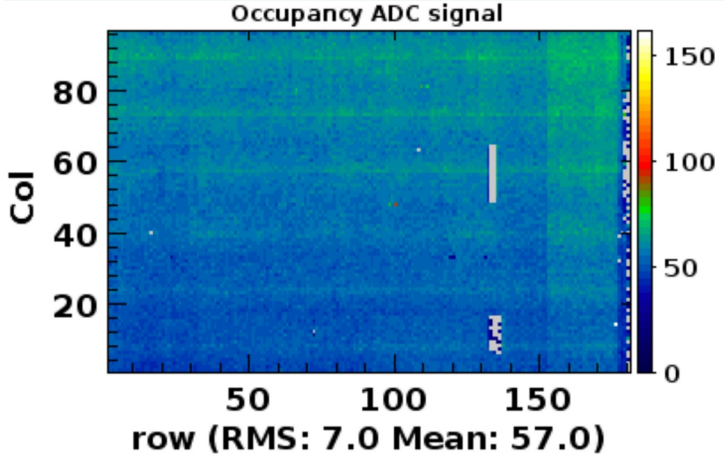








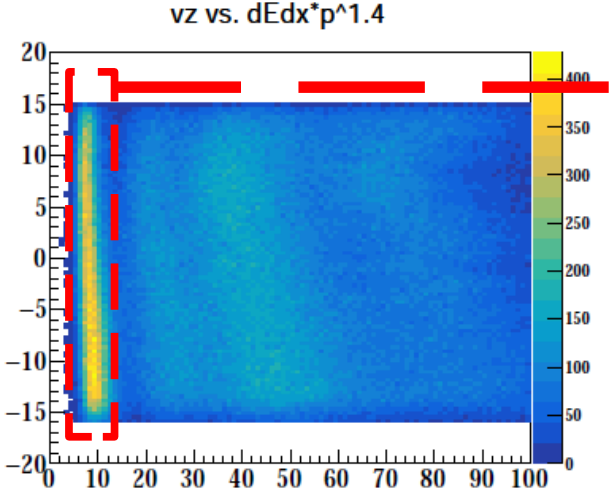
BONuS – Improving Gain Calibration

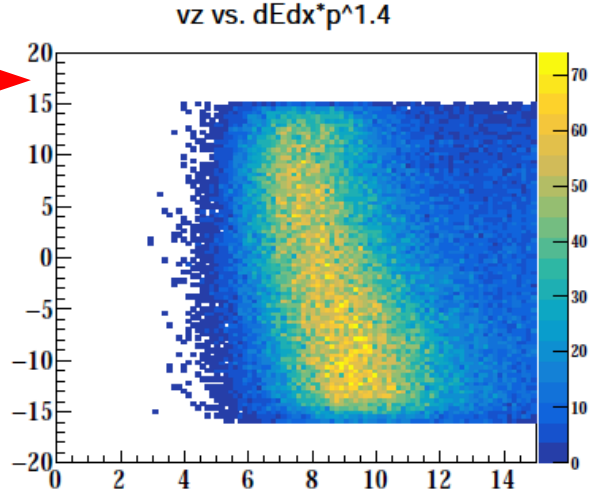


Signal height $\xrightarrow{\text{Pads' gains } (G_i)}$ $\left\langle \frac{dE}{dX} \right\rangle = \frac{\sum_i \frac{ADC_i}{Gi}}{vtl}$

→ Using real data pads' occupancy info, each pixel gives the ratio of the ADC sum for a given pad divided by the number of hits on that pad, which defines a pad "gain".

→ This method **did not correct** for an observable dependence of dEdx of the recoils on the longitudinal position along the target.





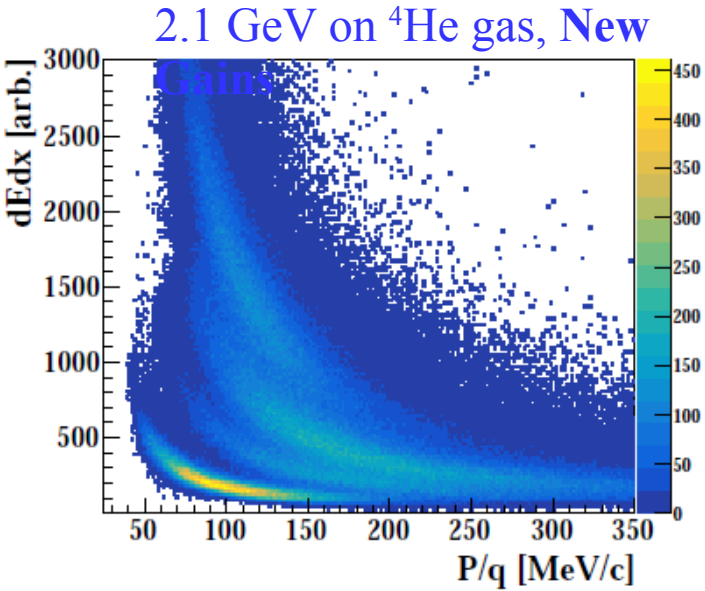
BONuS – Improving Gain Calibration

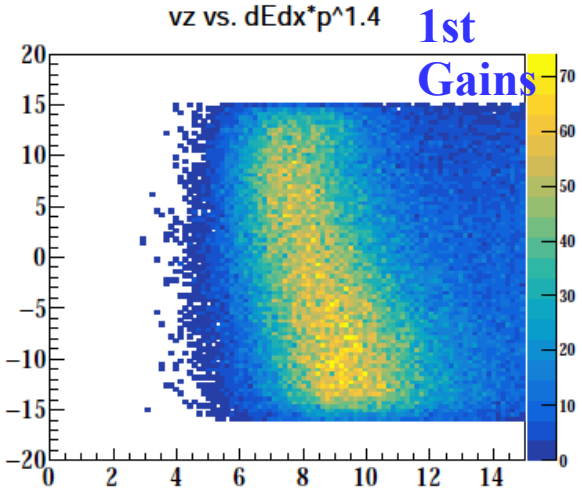
→ Using On-time reconstructed tracks (that spans the full drift region from the Cathode to the Anode)

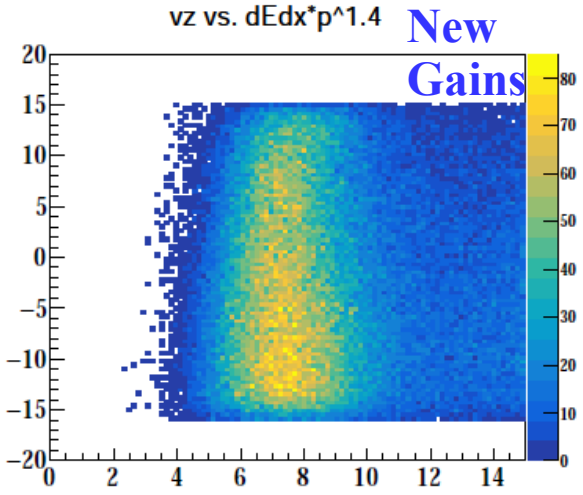
→ Comparing every pad's collected charge (ADCs) in a track to the median full track's collected charge.

→ Average this ratio (pad's gain) over enough statistics for every pad.

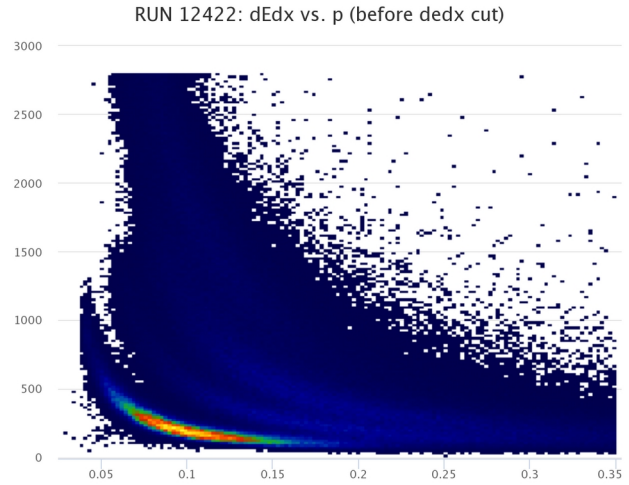
→ This method **has corrected** for the vz-dependance.

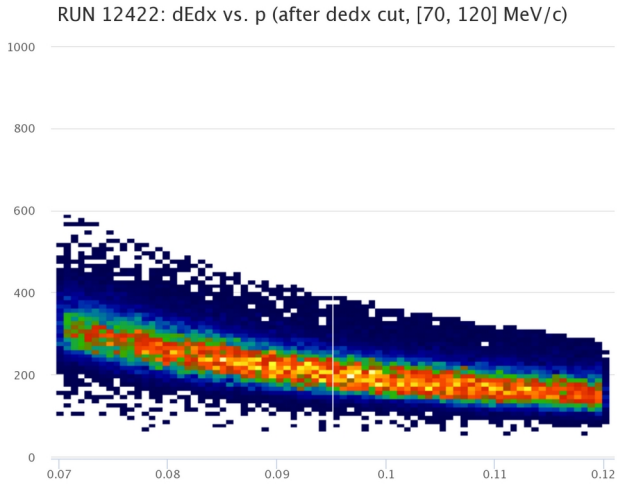


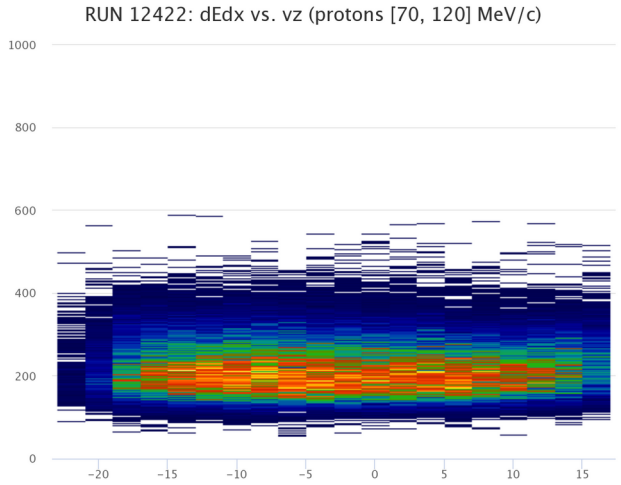


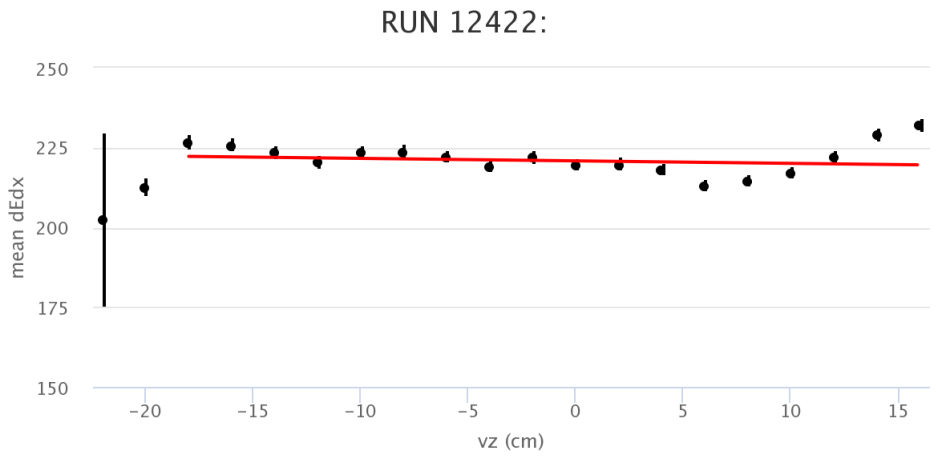


BONuS – dEdx Timelines









dEdx timelines Observables: using protons from all the target types:

- dEdx amplitude: the constant of the fit.
- dEdx slope vs. vz: the slope of the fit.
- dEdx percentage ratio:
  = target_length*slope/constants
