

Extractions of Σ and G asymmetries for $\pi^- p$ channel with Linear pol data

Study with Maximum Log-Likelihood method

T. Kageya @ g14 meeting, Jun. 24th 2021

Maximum Log-Likelihood method (No.1)

$$L_i = C_i [1 + P_b \Sigma \cos(2\phi_i) - P_T P_b G \sin(2\phi_i)] A_i \quad (1) \quad C_i : \text{Flux} \quad A_i : \text{Acceptance}$$

$$L_T = \prod L_i \quad (2) \quad \prod : \text{product operator}$$

$$\log L_T = \log (\prod L_i) = \sum \log \{C_i [1 + P_b \Sigma \cos(2\phi_i) - P_T P_b G \sin(2\phi_i)] A_i\} \quad (3) \quad \log(xy) = \log x + \log y$$

$$\log \{C_i [1 + P_b \Sigma \cos(2\phi_i) - P_T P_b G \sin(2\phi_i)] A_i\} = \log C_i + \log [1 + P_b \Sigma \cos(2\phi_i) - P_T P_b G \sin(2\phi_i)] + \log A_i \quad (4)$$

$$\log L_T = \log \prod C_i + \sum \log [1 + P_b \Sigma \cos(2\phi_i) - P_T P_b G \sin(2\phi_i)] + \log \prod A_i \quad (5)$$

Eq. (5) can be **differentiated** to find the maximum with respect to Σ or G

Constant terms: $\log \prod C_i$ and $\log \prod A_i$ don't have to be considered

Maximum of the term $\sum \log [1 + P_b \Sigma \cos(2\phi_i) - P_T P_b G \sin(2\phi_i)] \rightarrow$ obtain Σ and G

Maximum Log-Likelihood method (No.2)

From each event, input P_b , ϕ_i and P_T to $\log [1 + P_b \Sigma \cos(2\phi_i) - P_T P_b G \sin(2\phi_i)]$ for PERP
and to $\log [1 - P_b \Sigma \cos(2\phi_k) + P_T P_b G \sin(2\phi_k)]$ for PARA

Use Minuit to minimize by multiplying -1
to $\log L_T = \sum \log [1 + P_b \Sigma \cos(2\phi_i) - P_T P_b G \sin(2\phi_i)] + \sum \log [1 - P_b \Sigma \cos(2\phi_k) + P_T P_b G \sin(2\phi_k)]$

Minuit gets to minimum $\rightarrow$ gets maximum of $\log L_T$

Maximum Log-Likelihood method (No.3)

Followings are expected;

- (1) Errors are reduced to $\sim 70\%$ of the Least Square method ($\sim 30\%$ smaller error)
- (2) Final W bins $\rightarrow$ can compare ours with g13b results
may cover 6 W bins
- (3) Better performances for low statistic data than Least Square method

Maximum Log-Likelihood method (No.4)

- a) Example 1: generate the second polynomial distribution with random numbers
Apply the maximum log likelihood to the distribution
- b) Apply MLL to g14 data to extract Σ and G asymmetries

a) Example 1: generate the second polynomial distribution with random numbers

New !

1. Generate random numbers to have second polynomial distribution of $Y = 1 + 0.5x + 0.5x^2$ ($-1 < x < 1$)
2. Set a model to the distribution; $Y = 1 + aX + bX^2$
3. Each X_i data input to $L_i = 1 + aX_i + bX_i^2$ ($i = 1 - 2000$)
3. $L_T = \prod L_i$

a) Example 1: generate the second polynomial distribution with random numbers

a) Example 1: generate the second polynomial distribution with random numbers

2nd order of Polynomial

New !

b) Apply MLL to g14 data to extract Σ and G asymmetries

Data analysis

- (1) Use data from (PERP, + Target) and (PARA, + Target); correspond to $(1 + P_{\perp}^{+} \Sigma \cos(2\phi) - P_{+z} P_{\perp}^{+} G \sin(2\phi))$ and $1 - P_{||}^{+} \Sigma \cos(2\phi) + P_{+z} P_{||}^{+} G \sin(2\phi)$.
All cuts are applied including vertex cut
- (2) Apply cut of $-50 < \text{Coherent Edge} - E_g \text{ (MeV)} < 250 \text{ MeV}$ to select events with relatively well defined beam polarization.
6 final W bins as shown in the figure at the next page.
- (3) Empty target subtractions are not applied; instead about 7 % of corrections of dilution factors are applied.

Final W distributions and bins

New !

Final W
(GeV)

Σ asymmetries for $1.98 < fW < 2.06$ GeV

New!

Σ asymmetries on ϕ , $1.98 < W < 2.06$ GeV, $-0.05 < \text{DifEdgeEg} < 0.15$ GeV

Σ asymmetries for $2.06 < fW < 2.14$ GeV

New!

Σ asymmetries on ϕ , $2.06 < W < 2.14$ GeV, $-0.05 < \text{DifEdgeEg} < 0.25$ GeV

Σ asymmetries for $2.14 < fW < 2.22$ GeV

New!

Σ asymmetries on ϕ , $2.14 < W < 2.22$ GeV, $-0.05 < \text{DifEdgeEg} < 0.25$ GeV

Σ asymmetries for $1.9 < fW < 1.98$ GeV

New !

Σ asymmetries on ϕ , $1.9 < W < 1.98$ GeV, $-0.05 < \text{DifEdgeEg} < 0.25$ GeV

Σ asymmetries for $2.22 < fW < 2.3$ GeV

New!

Σ asymmetries on θ , $2.22 < W < 2.3$ GeV, $-0.05 < \text{DifEdgeEg} < 0.25$ GeV

Σ asymmetries for $1.82 < fW < 1.9$ GeV

Σ asymmetries on θ , $1.82 < W < 1.9$ GeV, $-0.05 < \text{DifEdgeEg} < 0.25$ GeV

New!

Maximum Log-Likelihood method (more understanding)

Separately analyze PERP and PARA;

$$\log L_T = \sum \log [1 + P_b \sum \cos(2\phi_i) - P_T P_b G \sin(2\phi_i)] \quad \text{for PERP data}$$

$$\log L_T = \sum \log [1 - P_b \sum \cos(2\phi_k) + P_T P_b G \sin(2\phi_k)] \quad \text{for PARA data}$$

Minuit gets to minimum $\rightarrow$ gets maximum of $\log L_T$, separately

Σ asymmetries for $2.06 < fW < 2.14$ GeV (analyzed PERP and PARA separately)

New!

Σ asymmetries on ϕ , $2.06 < W < 2.14$ GeV, $-0.05 < \text{DifEdgeEg} < 0.25$ GeV

Φ distributions for PARA after all cuts applied

New !

phi of piminus after all cuts

Φ distributions for AMO after all cuts applied

New !

phi of piminus after all cuts

Fiducial distributions for π^- (Last 4 data, PERP, no cuts applied)

sector 3 occupancy **Sector 3**

Thera vs Phi for pi-

$\cos(20) = 0.94$

$\cos(33) = 0.84$

ϕ

Σ asymmetries for $2.06 < fW < 2.14$ GeV

New!

Σ asymmetries on ϕ , $2.06 < W < 2.14$ GeV, $-0.05 < \text{DifEdgeEg} < 0.25$ GeV

Application of Maximum Log-Likelihood method to g14 data

(1) Analyze same numbers of events from **PERP** and **PARA** (shown above)

Using

$$\log L_T = \sum \log [1 + P_b \Sigma \cos(2\phi_i) - P_T P_b G \sin(2\phi_i)] + \sum \log [1 - P_b \Sigma \cos(2\phi_k) + P_T P_b G \sin(2\phi_k)]$$

Use Monte Carlo (simply using random numbers) to check (I have a simple and Nick has more advanced (generate for ϕ , Σ and G)).

(2) Separately analyze data,
for example PERP,

$$\log L_T = \sum \log [1 + P_b \Sigma \cos(2\phi_i) - P_T P_b G \sin(2\phi_i)] / \int_{-\pi}^{\pi} (1 + P_b \Sigma \cos(2\phi) - P_T P_b G \sin(2\phi)) d\phi$$

the term of $\int_{-\pi}^{\pi} (1 + P_b \Sigma \cos(2\phi) - P_T P_b G \sin(2\phi)) d\phi$ covers the acceptance issues

Example : generate hist like g14 and use MLL

$Y = C(1 + 0.5 \cdot \cos(2\phi) - 0.5 \cdot \sin(2\phi))$ generated shown in histogram
