

# Exclusive $\pi^0$ with JLab Hall C

Avnish Singh

Supervisor: Prof. Tanja Horn

# NPS Run Group 1a (Sept 2023 - May 2024)

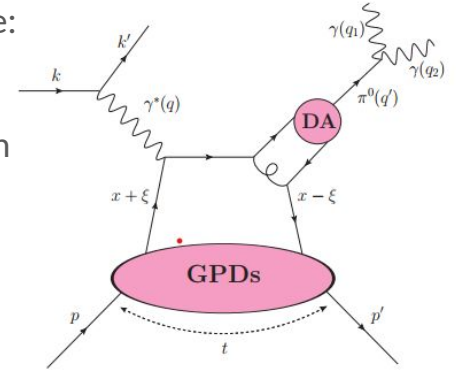

- [E12-13-010](#): Exclusive Deeply Virtual Compton and Neutral Pion Cross-Section Measurements in Hall C
- **E12-13-007**: Measurement of Semi-Inclusive  $\pi^0$  Production as Validation of Factorization
- **E12-22-006**: Deeply Virtual Compton Scattering off the neutron with the Neutral Particle Spectrometer in Hall C
- **E12-23-014**: Measurements of the Ratio  $R = \sigma_L/\sigma_T$ , p/d ratios, Pt dependence, and azimuthal asymmetries in Semi-Inclusive DIS  $\pi^0$  production from proton and deuteron targets using the NPS in Hall C

# E12-13-010: Exclusive Deeply Virtual Compton and Neutral Pion Cross-Section Measurements in Hall C

Complement the kinematic settings of Hall A, by one or two conjugate setting. Increases the  $Q^2$  reach to even higher values at fixed  $x_B$ . Expands the kinematic coverage to smaller values of  $x_B$ .

- $\pi^0$  electroproduction complements other channels for studying the nucleon structure:
  - **No diffractive p contributions:** Cleaner signal, reducing complications from vector mesons.
  - **No exclusive pole contributions:** Focuses the analysis purely on the production mechanisms without interference.
  - **Reduced resonance contributions:** Resonances play a smaller role, allowing access to more fundamental processes.
- Motivation for  $\pi^0$  electroproduction towards GPDs:
  - Sensitive to transversity GPDs ( $\tilde{H}_q, \tilde{E}_q$ ), which are less accessible in vector meson production.
  - Offers insights into parton helicity flipping (chiral-odd GPDs).
  - No need for polarized targets or beams to access these polarized distributions.

- Fig. from arXiv:2011.11125v2

# Physics Motivation: Exclusive $\pi^0$ Electroproduction

- **Measurements** of exclusive  $\pi^0$  electroproduction in the valence region have been performed by **Hall A** and the **CLAS Collaboration**.
- Hall A results suggests **dominant contributions from transversely polarized virtual photons ( $\sigma_T$ )**
- **Significant LT and TT interference terms** were also observed, highlighting the complex structure of the reaction mechanism.
- Measuring **longitudinal-transverse (L/T) separated cross sections** offers a **clean probe of transversity effects** in pion electroproduction.
- However, **no L/T-separated  $\pi^0$  data** currently exists **above the resonance region**, and **theoretical predictions** in this regime remain highly uncertain.
- If a **large  $\sigma_T$**  is confirmed at higher  $Q^2$  and  $W$ , it could open the door to a **detailed study of transversity GPDs**—an essential but elusive piece of the nucleon structure puzzle.
- Meanwhile, the **longitudinal cross section  $\sigma_L$** , if isolated, could provide a **unique channel to access the usual chiral-even GPDs** via **neutral pion production**.

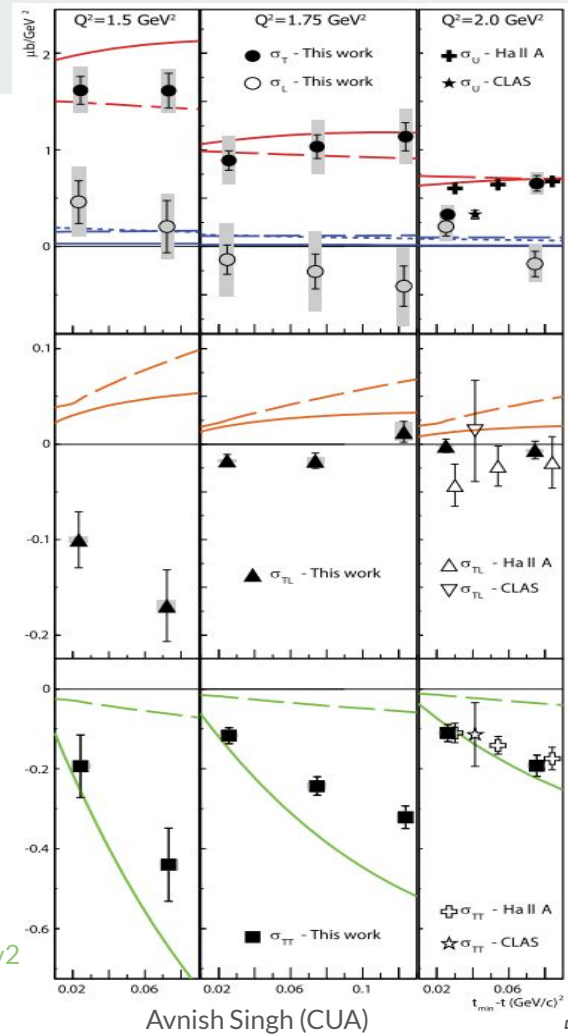

- Fig. from arXiv:2011.11125v2

# Previous Hall A Results: $\pi^0$ Electroproduction at Moderate $Q^2$

- Hall A experiment E07-007 measured exclusive  $\pi^0$  electroproduction cross sections at  $x_B=0.36$  and  $Q^2=1.5, 1.75, 2.0 \text{ GeV}^2$  [1].
- Achieved L/T separation of the differential cross section  $d\sigma/dt$ .
- Longitudinal component  $d\sigma_L/dt$  was found to be small or consistent with zero, but compatible with leading-twist chiral-even GPD models.
- Theoretical models including transversity GPDs are also in agreement with the data, particularly at higher  $Q^2$ .
- Supports theoretical predictions involving chirally enhanced helicity-flip pion distribution amplitudes.
- Provides strong motivation to pursue  $\pi^0$  studies at higher  $Q^2$  and  $W$  to further explore transversity GPDs.

- Fig. from arXiv:2011.11125v2

# Neutral Particle Spectrometer in Hall C - Overview

- Neutral Particle Spectrometer replaces one of the Hall C focussing spectrometers in the experiments
  - Angle reach between 5.5 and 60 degrees.
  - HMS has been recommissioned for 12 GeV
- Small angle, precision cross-sections, LT separation, high luminosity
- 1080 PbWO4 blocks.
- Radiation hard and temperature controlled frame.

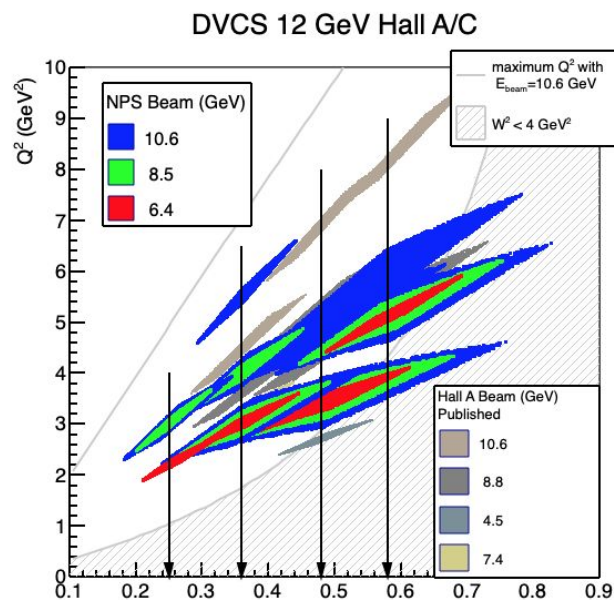

**E12-13-010 and E12-13-007**

# Current Analysis Workflow Overview:

- ✓ HCANA decoding → ROOT ntuples
  - Ingesting skimmed root files for analysis.
- ✓ Event cuts (HMS/NPS) in C++/ROOT
  - Working cuts based on known good acceptances, detailed study to be done.
- ✓ Random-timing &  $\emptyset$ -cluster background
  - Spline fit/Non-gaussian distribution background is shifted under the main coincidence peak and then subtracted to remove accidentals.
- ✓ Dummy LH<sub>2</sub>/LD<sub>2</sub> subtraction
  - Taking the Dummy target contribution for the setting and using the charge normalization to subtract.
- ✓ BCM charge Normalization & live-time scaling
  - Applying overall charge normalizations (some done in previous steps) and also introducing the necessary efficiency scaling
- ❑ Extraction of experimental yield (in progress)
  - Comparison of the observed data with the Hall C simulation framework SIMC.
  - Optimization of neutral pion cross section and spectrometer models.
- ❑ Outlook
  - Extraction of the **unseparated and separated cross-section** (multi-dimensional binning), cross-section **systematic uncertainties**, study of the **t-/Q<sup>2</sup>-dependence of the cross section**

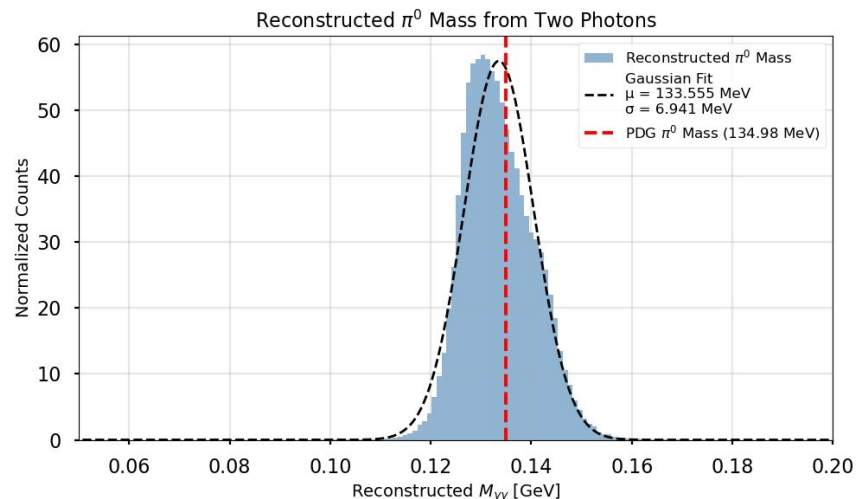

# Background Subtraction for $\pi^0$ Reconstruction

- Timing resolution precise enough to observe the 2ns beam bunching.
- Background arises from accidental photon pairs, misidentified clusters, and non-exclusive processes.
- We employ complementary approaches to model and subtract background beneath the  $\pi^0$  peak:
- Non-Gaussian (Moyal) distribution fit:
  - Captures asymmetric, Landau-like tails typical of calorimetric background.
  - Provides an analytic form that smoothly transitions across the spectrum.
- Spline fit method:
  - A data-driven, non-parametric approach using smooth cubic splines to trace the background shape.
  - Effective at modeling subtle variations not easily captured by analytic functions.

# $\pi^0$ Reconstruction via Invariant Mass

- Reconstructed  $\pi^0$  from two-photon invariant mass using cluster energies and opening angle from NPS.
- Invariant mass distribution shows a clear peak near 135 MeV, consistent with the neutral pion mass.
- Demonstrates successful identification of  $\pi^0$  candidates in the exclusive channel.
- Demonstrated high signal-to-background ratio, ensuring clean event selection for cross section extraction.

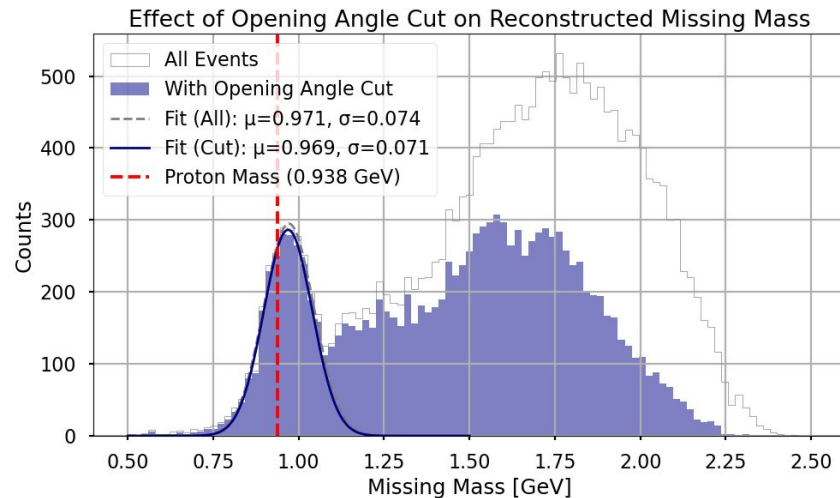

# Exclusive Channel Identification: Missing Mass off the Proton

- Use measured scattered electron (HMS) and reconstructed  $\pi^0$  (from NPS) to compute missing mass:

$$M_X^2 = (e + p - \pi^0)^2$$

- Expect a peak near proton mass ( $\sim 0.938$  GeV) for exclusive  $ep \rightarrow e'\pi^0 p'$  events.
- Missing mass spectrum shows clear signal, confirming exclusivity of selected events.
- Background includes:
  - Non-exclusive events (e.g., multipion production).
  - Mis-reconstructed clusters or mis-identified photons.
- Clean exclusive region used for final event selection in cross section analysis.

# Monte Carlo Status

Credit to Peter B.

- ❑ HallC uses the simulation framework called SIMC.
- ❑ Several models are available for PEEPI
  - Valery Kubarovsky (VK) GPD inspired fit for “deep”  $\pi^0$  (default when doing `pizero=TRUE`).
  - **param-04 (By Blok)** / **param-3000 (By T. Horn)** / **param-2021 (By P. Bosted)** for wider  $W, Q^2$ , latest phenomenological fit of global data by Peter B.
  - MAID 2007 multipole amplitudes below  $W \approx 2.2$  GeV.
  - Historic (1970s) Blok/Brauel fit.
- ❑ The code chooses which one to call based on  $W$ ,  $Q^2$  and the pion charge ( $\pi^+$ ,  $\pi^-$ ,  $\pi^0$ ).
- ❑ Takes a Monte-Carlo event, boosts it to the photon–nucleon CM, evaluates the appropriate  $\gamma N \rightarrow \pi N$  model cross-section there,
- ❑ Then multiplies Jacobian  $\times$  virtual photon flux, and hands SIMC the fully-differential electron pion coincidence cross-section in the lab.

# Preliminary Physics vs SimC Yield Comparisons

## □ Importing SIMC Flat File Events

- Loop over the file, reading one **header + 2 cluster** lines at a time.
- Increment **sum3** until the **ifstream** hits end-of-file (i.e. the trailer).
- Result: sum3 = number of events in that SIMC file.
- Read the  $\sigma_{cm}$  from last line of the file, sigcm is the third number

## □ Second Pass Event Loop

- Read the event record of two cluster lines  $\rightarrow (x,y,E)$  for  $\gamma_1$  and  $\gamma_2$ , plus unused (px,py,pz). Header[0]  $\rightarrow w\_evt$  (SIMC's per-event weight, counts / mC).
- Apply basic selection logic Per-cluster energy  $\geq 0.60$  GeV, cluster separation  $\geq 15$  cm.
- Calculate the  $\pi^0$  invariant mass  $m = m\_gg(\text{cluster1, cluster2, Ldet}=407 \text{ cm})$  or other desired physics variables via 4-vectors.

## □ Final Event Weighting

- Start with SIMC's own per-event weight ( $w\_evt$ ). Already in counts per milli-Coulomb (mC).
- Scale by a file-level normalization factor
 
$$normfac = \frac{\sigma_{cm}}{N_{events}}$$
- Scale by extra factor of  $\times 0.7$  if the file is exclusive or  $\Delta$ .
- Convert units to match workflow

# Closing Remarks

- Successfully reconstructed  $\pi^0$  invariant mass from NPS photon pairs and achieved **clean missing mass off the proton**, validating exclusive  $ep \rightarrow e' \pi^0 p'$  event selection.
- Implemented and cross-validated **background subtraction methods** (Moyal + spline) to isolate clean  $\pi^0$  signals across kinematics.
- Currently working on:
  - Extracting experimental yields in bins of  $Q^2$ ,  $x_B$ ,  $-t$ .
  - Comparison with SIMC simulations to correct for acceptance and radiative effects
- Next step: **Optimize pion production model in SIMC** for neutral pion channels
  - improves agreement between data and simulation and enables reliable cross section extraction
- Goal: Perform **L/T separation** of the cross section:
- Access  $\sigma_T$  and  $\sigma_L$ , and interference terms ( $\sigma_{LT}$  and  $\sigma_{TT}$ ).
- Essential for probing **transversity GPDs** ( $\sigma_T$ ) and **chiral-even GPDs** ( $\sigma_L$ ).
- This work contributes to the **next generation of hadron structure studies** using exclusive  $\pi^0$  production with the NPS in Hall C
